

# Landscape Ecological Potential

Author: JL Weber et al., EEA

Discussant: Lars Hein, Wageningen University

# Contents

- Introduction to NLEP
- Observations from the Discussant
- Questions for discussion

# Why ?

- Ecosystem accounting needs to be based on (among others) physical accounts of ecosystems and the benefits they provide
- Ecosystems, unfortunately, are very complex, diverse, and difficult to define and delineate.
- Simplified approach needed as a basis for physical (ecosystem) accounting
- Is this simplified approach the ‘Net Landscape Ecological Potential’ ?

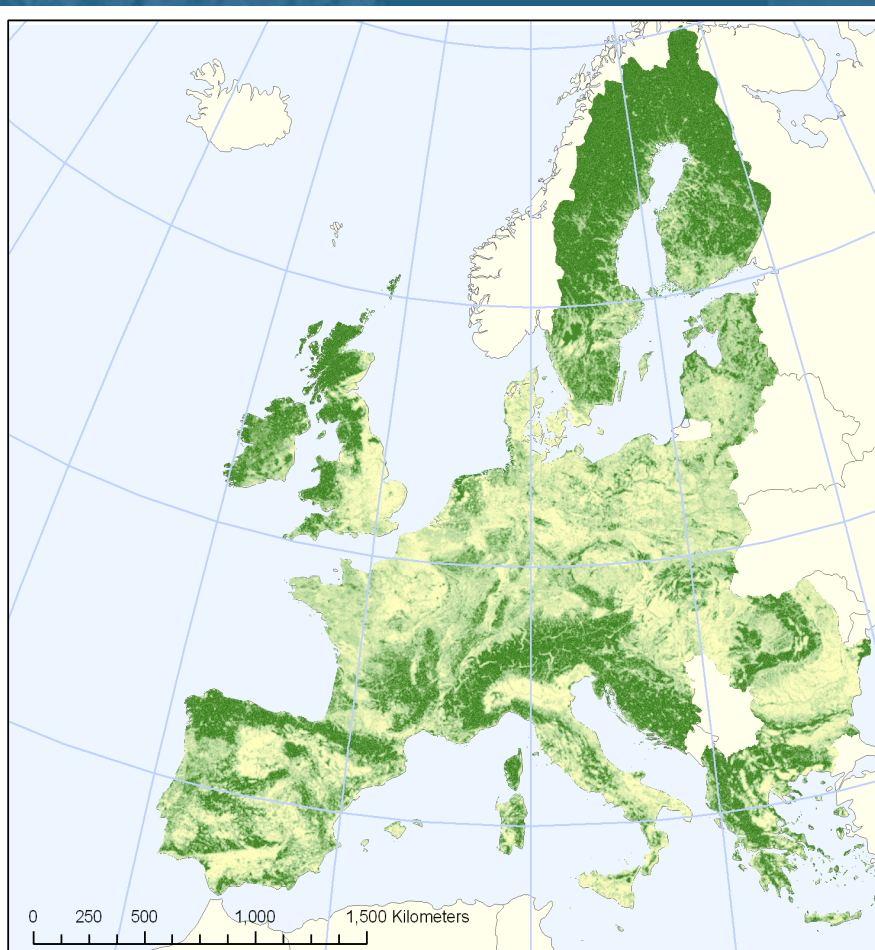

# What ?

- Net Landscape Ecological Potential (NLEP) developed by EEA ('Net Landscape Ecological Potential of Europe and change 1990-2000' – authors: JL Weber, R. Spyropoulou, T. Soukup, F. Paramo, April 2008)
- NLEP = Composite indicator for ecosystem integrity at the macro scale
- Developed by EEA for Europe for 1990 and 2000.
- Changes in NLEP reflect degradation or rehabilitation of ecosystems

# How ?

- $NLEP = f(\text{vegetation cover, protected status, fragmentation})$

# Vegetation Cover: Green Background Index (0-100)

## Legend

### Green Background Landscape Index 2000

GBLI, scale : 0 to 100

EEA/ETCLUSI  
from GBLI,  
NATURILIS  
and MEFF  
Methodology:  
EEA/ETCLUSI

European Environment A

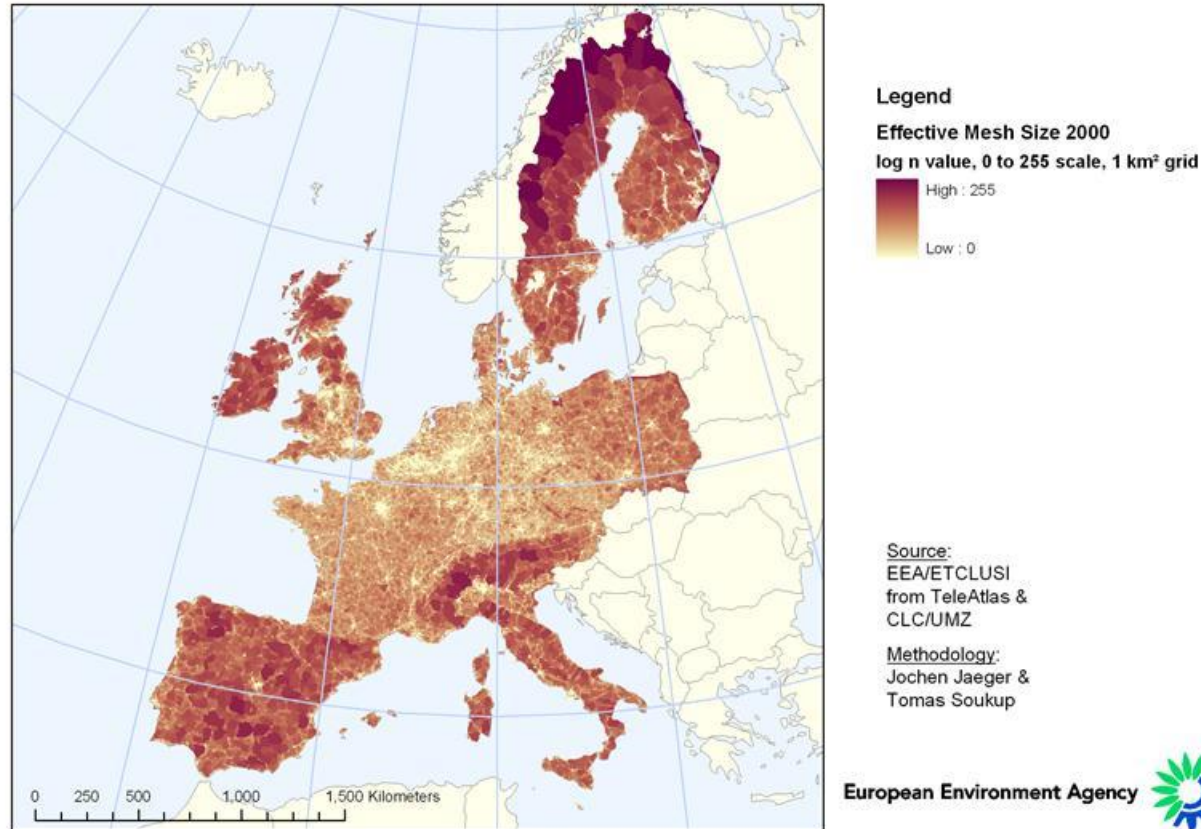

- Aggregation (and smoothing) of forests, pasture, inland waters, wetlands, semi-natural land and agricultural mosaics. Equal weighting ?

# Protected status (Naturalis Index) (0-100)

- Protected status, on the basis of designated sites (e.g. Natura2000, Ramsar) + high ecological value close to protected site (<5 km)

# Fragmentation (0-255)

- Reflects barriers to wildlife movement, roads, railways and constructions. The more barriers the lower the index value. Log conversion.

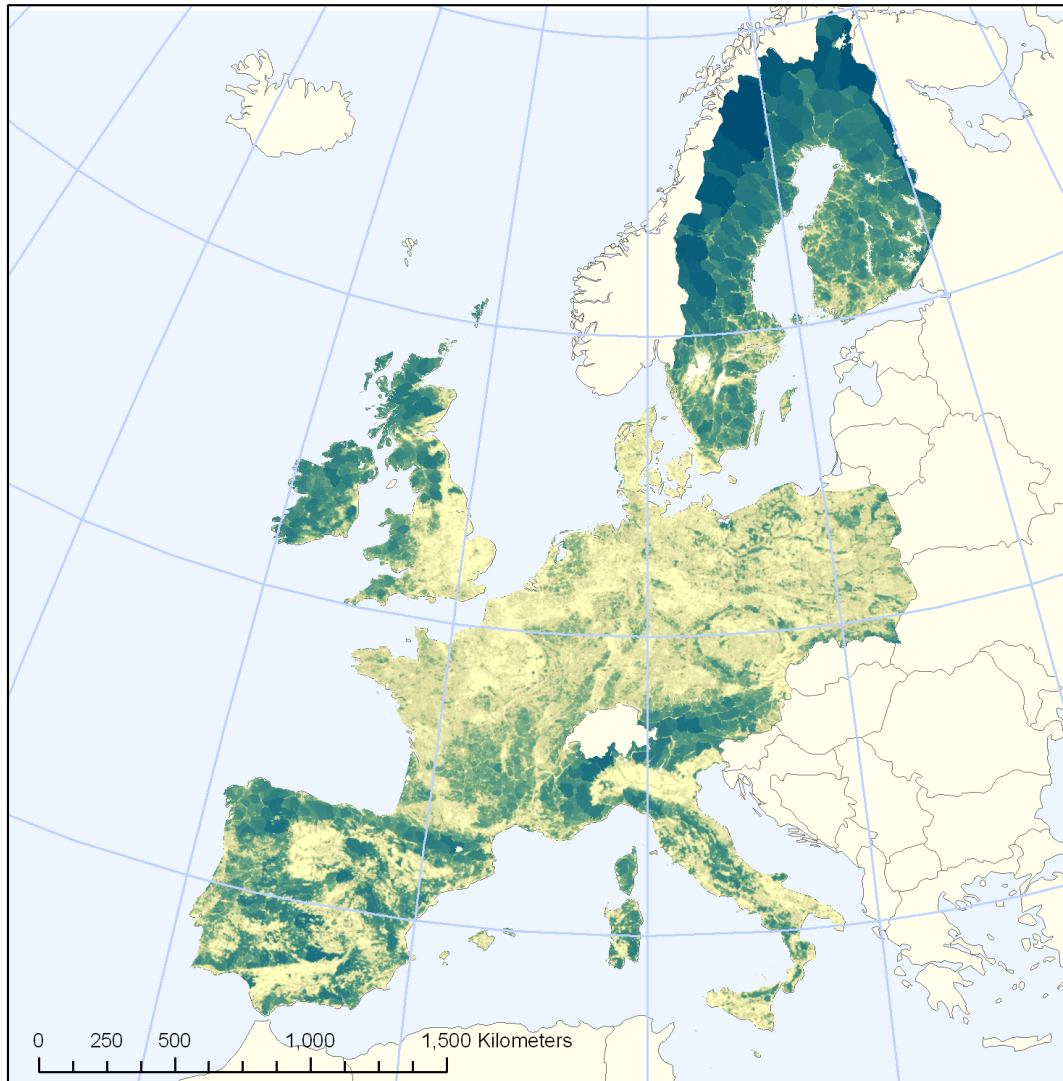

# Combined into: NLEP (0 to 255)

- GLEP = Green background Index + Naturalis Index (stretched from 0 to 255 ?)
- NLEP = sqrt (GLEP \* Fragmentation index)

$$NLEP = \sqrt{(vegetation\ index + protected\ index) \times fragmentation\ index}$$

# NLEP (1 km grid)

European Environment Agency

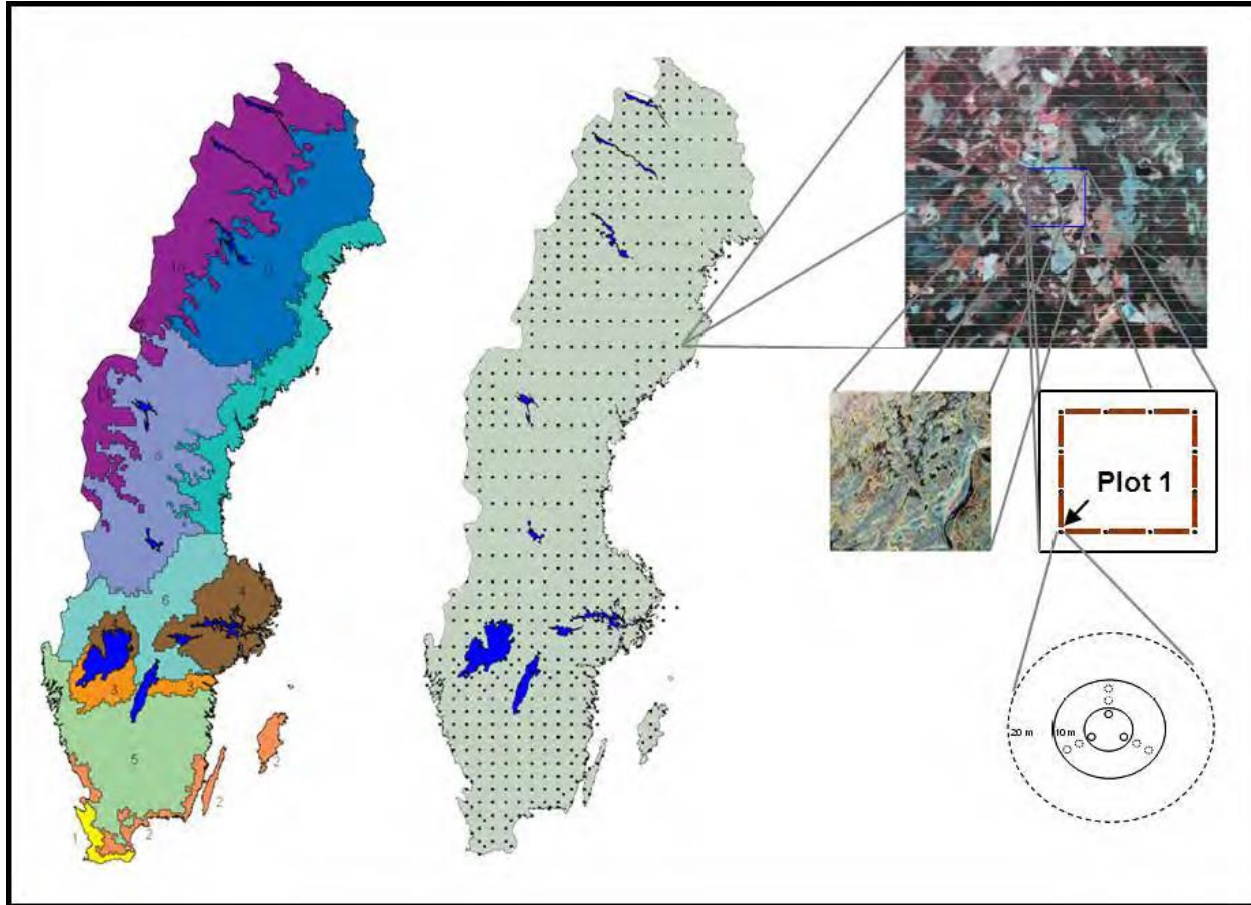

# Change in the NLEP 1990-2006

# Observations on the Methodology (1)

- Heavy weighting of Fragmentation, around twice as much impact as vegetation or protected status.
  - Not all species strongly affected by fragmentation (e.g. birds)
- Some choices appear subjective (log transformation of fragmentation, choice of 5 km form protected areas, equal aggregation of specific habitat types in the greenness maps)
- Why is fragmentation the difference between net and gross LEP ?

# Observations on the Methodology (2)

- No embedding of bottom-up / national data (e.g. EBONE Project / GEO)

# Observations on the Methodology (3)

- Index does not allow to analyse ecosystem or species diversity at a European scale (e.g. index may remain the same even if all wetlands are lost if this is compensated by forests)

# Observations on the Methodology (4)

- NLEP proposed as proxy for ecosystem integrity (*defined as ability of ecosystems to support biological communities comparable to natural habitat*)
- Ecosystem use not reflected in the NLEP, but NLEP may reflect the potential to supply ES.
- Relation between ecosystem integrity and the supply of (all?) ecosystem services unclear.

# Discussion questions

- Is the NLEP a correct indicator for ecosystem integrity ?
  - how can it be improved ?
- Will a reduction in NLEP lead to a loss of ES supply ?
  - Can NLEP be used to reflect the supply of some ecosystem services ?
- CAN NLEP serve the creation of physical accounts ?
  - Should we have a top-down approach (such as NLEP) or have a bottom-up approach (starting with ES supply and linking those to ecosystem properties) , or is there scope to test both approaches ?
- Where to go from here in defining ecosystem units/properties in support of establishing physical accounts ?
- What other questions do you have ?

# Question 1

- Is the NLEP a correct indicator for ecosystem integrity ?
  - how can it be improved ?
-

# Question 2

- Will a reduction in NLEP lead to a loss of ES supply ?
  - Can NLEP be used to reflect the supply of some ecosystem services ?

# Question 3

- CAN NLEP serve the creation of physical accounts ?
  - Should we have a top-down approach (such as NLEP) or have a bottom-up approach (starting with ES supply and linking those to ecosystem properties) , or is there scope to test both approaches ?

# Question 4

- Where to go from here in defining ecosystem units/properties in support of establishing physical accounts ?

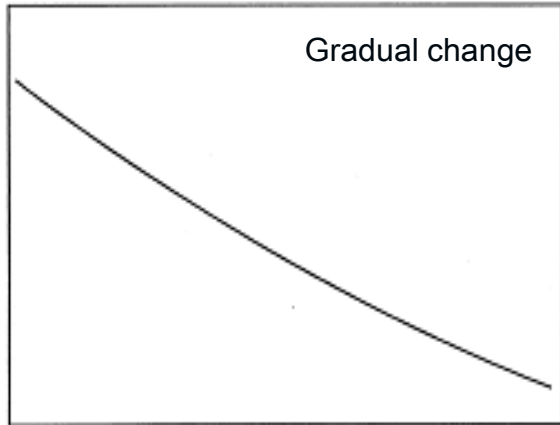

# Ecosystem change is complex
